Elementary Row Operations

- 1. Interchange two rows $(R_i \leftrightarrow R_j)$
- 2. Multiply one row by a nonzero number $(cR_i \rightarrow R_i)$
- 3. Add a multiple of one row to a different row $(cR_i + R_j \rightarrow R_j)$

Elementary row operations do not change the solution set. Thus we can solve a system of linear equations by the following *Gauss-Jordan Elimination procedure*:

- 1. Write the system as an augmented matrix.
- 2. Apply elementary row operations to transform the coefficient matrix into *reduced row echelon form.* Or, use a computer/calculator!
 - (a) Interchange rows, if necessary, to make the top left entry ("first pivot") non-zero.
 - (b) Divide Row 1 by the pivot to get "leading 1."
 - (c) Subtract multiples of Row 1 to achieve 0s beneath the first pivot.
 - (d) Interchange Row 2 with a later rows, if necessary, to make the the second entry of Row 2 ("second pivot") non-zero.
 - (e) Divide Row 2 by its pivot to get leading 1 in row 2.
 - (f) Subtract multiples of Row 2 to achieve 0s beneath the second pivot, etc.
 - (g) Continue this process until you run out of columns. At this point your matrix will be in *row echelon form*.
 - (h) Starting at the right-most leading 1, subtract multiples of that row to eliminate all entries in the column above the leading 1.
 - (i) Move to left to the next leading 1, perform the same procedure.
 - (j) Continue this process until you reach the first column.
- 3. Determine whether there is no solution, one solution, or infinitely many solutions. If there are infinitely many solutions, parameterize them by introducing a *free variable* for each column without a leading 1.

 $\frac{-2(19)}{2} = -2$

 $\begin{array}{c} 0 \\ \times +2y = 4 \\ 2y = 6 \\ 2y = 6 \\ 1y = 3 \\ 1y = 3 \\ y = 4 \\ y$
